Stereotactic Radiation (SRS, SBRT, SABR)

Stereotactic radiation is a type of external beam radiation therapy that administers very high doses of radiation to precisely target a tumor. Your radiation oncologist can tell you whether this approach is an option for your specific condition.

WHO IS QUALIFIED TO PROVIDE RADIATION THERAPY?
Radiation oncologists are highly trained, board-certified and licensed physicians who use radiation therapy in its various forms to care for patients with cancer and other conditions, and who oversee the care of each person undergoing stereotactic radiation. Radiation oncologists team up with neurosurgeons for stereotactic radiosurgery of the brain or spine.

Other members of the radiation therapy treatment team include medical physicists, dosimetrists, radiation therapists, and radiation oncology nurses.

To find a radiation oncologist go to www.rtanswers.org.

WHERE SHOULD I BE TREATED?
Modern radiation therapy facilities are widely available across the country. Not all of them offer every type of radiation treatment. You should choose a center that offers the most appropriate treatments for your particular condition. Possibilities include:

- Academic medical centers located at major universities across the country.
- Community hospital cancer centers.
- Freestanding radiation therapy or cancer centers.

The suitability of a given treatment center will depend on the specific treatment you require, the technical capabilities of the center, the experience of the physicians, and the center’s location. Your health insurance plan may limit your choices to certain preferred centers.

HOW DO I CHOOSE THE BEST TREATMENT FOR ME?
Choosing between treatments is confusing, and sometimes there is no simple answer. For many patients, there are several reasonable options. Factors to consider:

- Is reliable medical evidence available supporting the use of this treatment for your specific condition? This evidence may be hard to find for some new technologies.
- What are the side effects?
- Is it covered by insurance?
- Is travel required to get to the treatment?
- Have you had the opportunity to ask questions and had them answered to your satisfaction?
- Do you feel comfortable with the radiation oncologists?

THINGS YOU SHOULD KNOW:

- Your physician should discuss all of the appropriate, medically approved treatments related to your condition. You should be concerned if your doctor refuses to talk about other treatments.
- Question heavily advertised treatments not backed by scientific evidence.
- You can always seek a second opinion. No doctor should discourage you from getting one.

ABOUT ASTRO
The American Society for Radiation Oncology is the premier radiation oncology society in the world with more than 10,000 members who specialize in treating cancer with radiation therapy. ASTRO is dedicated to improving patient care through education, clinical practice, advancement of science and advocacy.

RADIATION THERAPY
Radiation therapy, sometimes called radiotherapy, involves the use of radiation to treat cancer and other diseases. Specially trained doctors called radiation oncologists use radiation to cure cancer, to stop a tumor from growing, or to relieve symptoms such as pain. Radiation has been used to treat cancer and other diseases for more than 100 years. External beam radiation therapy is the most common method for giving radiation therapy. Similar to an X-ray, external beam radiation therapy is delivered from a machine that doesn’t touch your skin. Your doctor directs the radiation beams to the tumor inside your body to destroy it. This works because tumor cells are unable to repair themselves after being damaged by radiation, unlike normal cells. Typical external beam radiation is given daily for several weeks. This allows doctors to deliver enough radiation to the cancer cells in your body, while allowing healthy cells time to recover.

STEREOTACTIC RADIATION THERAPY
A specialized type of external beam radiation therapy called stereotactic radiation uses focused radiation beams targeting a well-defined tumor. It relies on detailed imaging, computerized three-dimensional treatment planning and precise treatment set-up to deliver the radiation dose with extreme accuracy. There are two types of stereotactic radiation:

1. Stereotactic radiosurgery (SRS) delivers one to five stereotactic radiation treatments to the brain or spine. SRS is delivered by a team involving a radiation oncologist and a neurosurgeon. This treatment does not involve surgery. An incision is not made and tissue is not surgically removed.

2. Stereotactic body radiation therapy (SBRT) or stereotactic ablative radiotherapy (SABR) delivers one to five stereotactic radiation treatments to tumors within the body, excluding the brain or spine. SRS/SBRT/SABR is generally best for very small, well-defined tumors that can be seen on imaging such as CT or MR scans, thus this approach is not suitable for all situations. Also, the amount of radiation that may be safely delivered may be limited if the cancer is located close to a sensitive normal structure, such as the spinal cord or bowel.

These techniques allow doctors to give a high dose of radiation to the tumor in a short amount of time. SRS/SBRT/SABR is a type of external beam radiation therapy that can be completed in one to five treatments.

The advantage of SRS/SBRT/SABR is it delivers the right amount of radiation to the cancer in a shorter amount of time than traditional treatments. Plus the treatment is delivered with extreme accuracy, minimizing the effect on other nearby organs.

A disadvantage of SRS/SBRT/SABR is that this technique is suitable only for small, well-defined tumors that can be seen on imaging such as CT or MR scans, thus this approach is not suitable for all situations. Also, the amount of radiation that may be safely delivered may be limited if the cancer is located close to a sensitive normal structure, such as the spinal cord or bowel.

HOW ARE THESE TREATMENT SYSTEMS DIFFERENT?
• Different ways to achieve accuracy: Different systems use different imaging, computerized treatment planning and precise treatment set-up to deliver the radiation dose with extreme accuracy. There are two types of stereotactic radiation:
  1. Stereotactic radiosurgery (SRS) delivers one to five stereotactic radiation treatments to the brain or spine. SRS is delivered by a team involving a radiation oncologist and a neurosurgeon. This treatment does not involve surgery. An incision is not made and tissue is not surgically removed.
  2. Stereotactic body radiation therapy (SBRT) or stereotactic ablative radiotherapy (SABR) delivers one to five stereotactic radiation treatments to tumors within the body, excluding the brain or spine. SRS/SBRT/SABR is generally best for very small, well-defined tumors that can be seen on imaging such as CT or MR scans, thus this approach is not suitable for all situations. Also, the amount of radiation that may be safely delivered may be limited if the cancer is located close to a sensitive normal structure, such as the spinal cord or bowel.

CONDITIONS TREATED WITH STEREOTACTIC RADIATION
(Stereotactic radiosurgery (SRS) is used to treat conditions involving the brain or spine including:
• Cancers that recur in the brain (gliomas and other primary brain tumors).
• Cancers that spread to the brain (brain metastases).
• Benign tumors arising from the membranes covering the brain (meningiomas).
• Benign tumors of the pituitary (pituitary adenomas).
• Benign tumors of the inner ear (acoustic neuromas and vestibular schwannomas).
• Benign conditions of the cranial nerves (trigeminal neuralgia).
• Abnormal blood vessels in the brain (arteriovenous malformations).

Stereotactic body radiation therapy (SBRT) is used to treat small tumors in the chest, abdomen or pelvis that cannot be removed surgically or treated with conventional radiation therapy, including:
• Small lung cancers.
• Cancers that have started elsewhere and spread to the lung (lung metastases).
• Cancers that start in or spread to the liver (liver metastases).

These lists cover commonly treated conditions but do not include every possibility. Stereotactic radiation may be useful for other cancers not readily addressed with surgery or conventional radiation therapy. Patients with tumors that are small and few in number are the best candidates for stereotactic techniques. Not all patients can benefit from this type of treatment.

Other patients with more diffuse tumors, involved lymph nodes or tumors that have spread to other areas may also be candidates for stereotactic techniques.
